A panel of anti-glycan IgM antibodies for predicting the development of relapsingremitting multiple sclerosis after the first neurological event

M.S. Freedman, A. Miller, M. Schwarz, O. Weisshaus, R.T. Allstock, A. Duker, N. Dotan, C. Sindic (Ottawa, CAN; Haifa, Lod, IL; Brussels, B)

Background: There is an unmet need to develop specific serum based biomarkers for the diagnosis and prognosis of Relapsing Remitting MS (RRMS). We have reported that elevated levels of serum anti-Glc(alphal, 4) Glc(alpha) (GAGA4) IgM antibodies (Ab) exist in RRMS patients in comparison to patients with other neurological diseases (OND) enabling to discern which post-CIS patients convert to RRMS vs. OND. We have further investigate whether other anti glucose based IgM Ab may improve on the RRMS prediction for CIS patients. Aim: To evaluate the predictive value of IgM Ab against Glc(alpha1,6)Glc(alpha) (GAGA6), alpha-GICNAc (GNa), and GAGA4, for identifying patients with CIS that will evolve to RRMS or will have a more active disease. Methods: Retrospective analysis on of 88 frozen sera from CIS patients presenting for diagnostic work-up and were followed for a minimum of 4 years, Forty four patients were subsequently confirmed to have RRMS, whereas the other 44 developed OND (other inflammatory (OIND), n=23, or non-inflammatory neurological disease (ONIND), n=21). The groups were matched for gender composition, age and total IgM. Sera were diluted 1:1200 and levels of GAGA6, GAGA4 and GNa IgM Ab measured by enzyme immunoassay normalized to IgM levels. Results: Significantly higher levels of anti-GAGA6 IgM (p=0.01) and anti-GAGA4 IgM (p=0.005) Ab were observed in CIS patients who converted to RRMS as opposed to OND. Using the OND sample set and a cut-off of mean + 280 for anti GAGA6 and GAGA4, we have found that 17144 (39%) converting CIS patients were positive, whereas 42144 (95%) OND patients were negative for both Ab, corresponding to a sensitivity of 39%, a specificity of 95%, PPV of 89%, and NPV of 61%. In addition, higher levels of anti-GAGA4 and anti-GNa Ab (8 median) predicted a greater number of future attacks. RRMS patients with levels > median vs. patients with lower levels (< median) of antiGAGA4 and anti-GNa IgM antibodies went on significantly (16/20 (80%) vs. 10121 (47%), and 17120 (85%) vs. 9/21 (43%), (f02 test, p=0.025) odds ratio 4.4 (CI 95% 1.6-11.8), and odds ratio 7.5 (CI 95% 2.4-23.8), respectively to have further attacks within 2 years.

Conclusion: Measuring Anti-GAGA4 together with Anti-GAGA6 IgM yields higher sensitivity (39%), specificity (95%) and PPV (89%) of CIS patients evolving to RRMS. In Addition higher levels of IgM antibodies to the GAGA4 and GNa epitopes predicts at CIS which patients Will have imminent attacks.
